Operations Research

Homework 5

Due via Moodle (Pyomo) by Saturday, October 17, 2020

1. (This is a variation of Exercise 8.1-2 from HL.) The Childfair Company has three plants producing child push chairs that are to be shipped to four distribution centers. Plants 1, 2, and 3 produce 12, 17, and 11 shipments per month, respectively. Each distribution center needs to receive 10 shipments per month. The distance from each plant to the respective distribution centers is given below:

	Distribution Center					
	1	2	3	4		
Plant 1	800 miles	1300 miles	400 miles	700 miles		
Plant 2	1100 miles	1400 miles	600 miles	1000 miles		
Plant 3	600 miles	1200 miles	800 miles	900 miles		

The freight cost for each shipment is \$100 plus 50 cents per mile. The objective is minimizing the total cost of transportation.

- (a) Formulate and solve the problem in Pyomo.
- (b) Now suppose that demand in the area served by Center 1 goes up to 15 shipments per month. Production cannot be increased on short notice, so some or all of the distribution centers will be under-supplied. Modify your Pyomo code to determine the total number of shipments to arrive at each of the centers if the objective is still to minimize the overall cost of transportation.

Submit a commented printout (PDF) of your Ipython notebook showing code and output for each.

and 3, respectively, whereas Plants 4 and 5 do not have the capability for producing this product. Sales forecasts indicate that 600, 1000, and 800 units of products 1, 2, and 3, respectively, should be produced per day. Plants 1, 2, 3, 4, and 5 have the capacity to produce 400, 600, 400, 600, and 1000 units daily, respectively, regardless of the product or combination of products involved. Assume that any plant having the capability and capacity to produce them can produce any combination of the products in any quantity. Management wishes to know how to allocate the new products to the plants to minimize total manufacturing cost.

- (a) Formulate this problem as a transportation problem.
- (b) Use Pyomo to obtain an optimal solution.

Part (a) should be submitted handwritten on paper or typed into the Ipython notebook using mathematical markup; for part (b) submit a printout (PDF) of your Ipython notebook showing code and output.

3. (From HL, Problem 8.3-2.) Four cargo ships will be used for shipping goods from one port to four other ports (labeled 1, 2, 3, 4). Any ship can be used for making any one of these four trips. However, because of differences in the ships and cargoes, the total cost of loading, transporting, and unloading the goods for the different ship-port combinations varies considerably, as shown in the following table:

	Port				
	1	2	3	4	
Ship 1	\$500	\$400	\$600	\$700	
Ship 2	\$600	\$600	\$700	\$500	
Ship 3	\$700	\$500	\$700	\$600	
Ship 4	\$500	\$400	\$600	\$600	

The objective is to assign the four ships to four different ports in such a way as to minimize the total cost for all four shipments.

(a) Let $x_{ij} = 1$ if ship *i* is sent to port *j* with $x_{ij} = 0$ otherwise. (A problem of this form is called an assignment problem.) Formulate and solve this problem in Pyomo. You should submit a printout of your Ipython notebook showing code and solution.

Hint: In Pyomo, you can declare a variable to take only values 0 and 1 by using the option within=Boolean.

(b) Now suppose you drop the requirement that the x_{ij} are Boolean and replace it with the usual non-negativity requirement. In other words, you are allowing to send "a fraction of a ship" to one port and another fraction to another. Re-solve the problem in Pyomo. What do you see?
