

1.5 Spot Rates

General idea: yields/interest rates should be different for different maturities

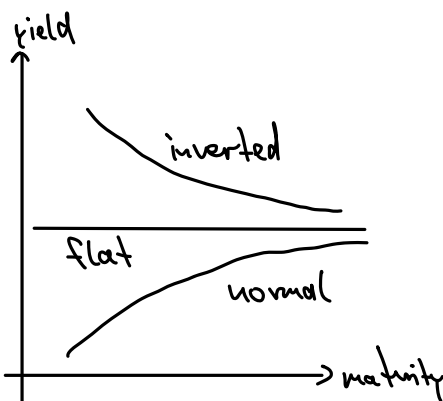

Usually: longer commitment (maturity) \Rightarrow higher interest

This phenomenon is called "term structure".

A "normal" yield curve:

Other common types of curves:

Spot rate $S(i)$ = yield to maturity of i -period zero-coupon bond

(they follow the relation $P = \frac{F}{(1+S(i))^i}$)

\Rightarrow **Spot rate curve** is the zero-coupon bond yield curve

Suppose the $S(i)$ are given by some standard, say, in the US the US-treasury zero-coupon bonds, then a better level-coupon bond price formula would be

$$P = \sum_{i=1}^n \frac{C}{(1+S(i))^i} + \frac{F}{(1+S(n))^n} \quad (n=1 \text{ here})$$

note: $d(i) := \frac{1}{(1+S(i))^i}$ are called **discount factors**.

note: risky bonds should be cheaper, this is often taken into account by adding a "static spread" s : $(1+S(i))^{-i} \rightarrow (1+s+S(i))^{-i}$

side remark: there is also the concept of **forward rates**:

consider 0-coupon bond

$$\text{Timeline: } \begin{array}{c} | \text{-----} | \rightarrow \\ | \quad \quad \quad | \\ | \quad \quad \quad j \end{array} \quad FV_j = P (1+S(j))^j$$

$$\text{Timeline: } \begin{array}{c} | \text{-----} | \rightarrow \\ | \quad | \quad \quad | \\ | \quad i \quad \quad j \end{array} \quad FV_i = P (1+S(i))^i$$

$$\begin{aligned} \Rightarrow FV_j &= FV_i (1+S(i,j))^{j-i} \\ &= P (1+S(i))^i (1+S(i,j))^{j-i} \end{aligned}$$

$S(i,j) = (j-i)$ -period spot rate i periods from now (unknown)
(there are many models for $S(i,j)$)

Sometimes the simple model of (implied) forward rates is used:

$f(i;j)$ = model for $S(i;j)$ based on

$$(1 + S(i;j))^j = (1 + S(i;i))^i (1 + f(i;j))^{j-i}$$

$$\Rightarrow f(i;j) = \left(\frac{(1 + S(i;j))^j}{(1 + S(i;i))^i} \right)^{\frac{1}{j-i}} - 1$$
